

RAGShield

Reliability Framework for RAG Systems
Debugging, audit and finalisation report (two audit passes)

Prepared 07 October 2026

Headline (group-held-out)	Before: v1, template-group split, Layers 1+2	After: v3, lineage split, Layers 1+2 (no judge)	After: v3, lineage split, full hybrid (live judge)
Precision	0.767	0.955	0.992
Recall	1.000	0.848	0.976
F1	0.868	0.898	0.984
False positive rate	0.875	0.057	0.011
Attack lineages leaking into training	present	0	0
Legitimate real-document chunks quarantined without review	19 / 34 (56%)	0 / 34	0 / 34

'Before' is the shipped repository evaluated with the same script and no LLM judge. The two 'After' columns use the same lineage-grouped folds: Layers 1+2 alone (0.5 cutoff in place of the judge) and the full hybrid with the live Groq judge (openai/gpt-oss-20b; 118 judge calls in cross-validation, 0 failures). Only like-for-like columns should be compared. Section 13 covers the second audit.

1. Executive summary

RAGShield is a three-layer prompt-injection firewall that sits between a FAISS retriever and the answer-generating LLM. Layer 1 is a deterministic heuristic scanner, Layer 2 an embedding classifier (all-MiniLM-L6-v2 → logistic regression), Layer 3 a contextual LLM judge on Groq. The central design idea is that **instructional language is not prompt injection**: manuals, policies and support articles are full of instructions for humans, whereas an injection is text that tries to steer the downstream AI.

The repository as shipped had three interacting problems. The classifier had been trained on 40 single-sentence benign examples against 115 attacks, so it scored ordinary document prose at 0.7 or higher. The firewall had regressed to blocking anything above 0.7 without consulting the judge. And the group-held-out evaluation collapsed to 31 false positives out of 31 when the single benign style was held out. Together these meant that a normal PDF full of procedures would have had more than half of its text quarantined silently.

First audit fixes: the benign side of the benchmark was extended with 48 realistic multi-sentence document chunks in eight domains; benign records are additionally trained at sentence level so max-sentence scoring judges units the model has seen; the routing table was unified so a high ML score alone never blocks and Layer 1 evidence forces a judge review; Layer 1 gained Unicode normalisation and base64 rescanning; two evaluation leaks were closed; judge failures are counted separately; both LLM prompts were hardened. Thresholds (0.30 / 0.70) were not changed.

A second audit (section 13) then traced attack lineage through the benchmark: all attacks descend from 21 seed sentences, and the original group split let a seed sit in training while its wrapped or paraphrased form sat in test. The benchmark now carries an explicit lineage_id, evaluation groups on it, ten genuinely novel indirect payloads were added, and the honest numbers are lower than the first report's: recall 0.848 instead of 0.887, and the classifier detects only 1 of 10 novel indirect payloads. A Layer 1 rule for text that addresses the AI now escalates 9 of those 10 to the judge, so no attack in leakage-free cross-validation passes without Layer 3 review. The Groq request configuration was corrected against current documentation and all dependencies were pinned to the versions the model was trained with.

Verification: 87 unit tests and 2 real-document tests pass; every evaluation script was rerun on the final code and model; the Streamlit app was driven end to end in a headless browser. Layer 3 was exercised live on Groq (openai/gpt-oss-20b): 118 judge calls in lineage-grouped cross-validation and 20 on the random split, with 0 failures.

2. Architecture and routing

Documents → chunking (500 chars, 50 overlap) → MiniLM embeddings → FAISS retrieval → **RAGShield firewall** → sanitised context → answer LLM. The same routing function (firewall.screen_chunks) is used by the Streamlit app and by every evaluation condition.

Layer 1 result	Layer 2 probability	Decision	LLM call
critical rule matched	not scored	BLOCKED	no
no match	< 0.30	SAFE	no
any match	≥ 0.70	BLOCKED (two independent layers agree)	no
anything else	anything else	Layer 3 judge decides: SAFE → included (shown as REVIEW); INJECTION or any judge failure → BLOCKED	yes

A **high Layer 2 score alone never blocks**, because legitimate manuals and policies score high. A **low Layer 2 score does not pass if Layer 1 found evidence**: base64 payloads, homoglyph text and text that addresses the AI score low for the classifier but leave detectable traces. Layer 3 fails closed with a labelled error class.

3. First-audit findings

Issue	Severity	File(s)	Evidence	Fix applied
Routing regression: ML $\geq$ 0.7 hard-blocked with no judge	Critical	firewall.py, config.py	19 of 34 real-document chunks scored $\geq$ 0.7 $\rightarrow$ 56% of legitimate text quarantined without review	Unified routing table (section 2)
Classifier scored legitimate prose 0.71–0.78	Critical	ml_classifier.py, benchmark	Reproduced (password-reset sentence = 0.767); 40 single-sentence benign vs 115 attacks	Benchmark v2 (+48 realistic benign chunks); sentence-level benign training units
Group-held-out collapse	Critical	benchmark	benign_seed fold 31 FP / 0 TN; no-LLM aggregate FPR 0.875	Same as above; FPR now 0.057 under the stricter lineage split
Critical heuristic fired on a benign record	High	heuristics.py	'Disregard the earlier estimate...' hard-blocked	Rule requires an instruction noun
Obfuscated attacks passed silently below LOW	High	firewall.py, heuristics.py	6 base64/homoglyph records scored < 0.30; Layer 1 evidence unused	Any Layer 1 match forces a judge review; zero-width stripping, confusable folding, base64 rescan
Category-held-out trained on its own benign test rows	High	run_evaluation.py	train set excluded only the attack category	Benign test records excluded from training
Main evaluation scored with the saved production model	Medium	run_evaluation.py	Loaded CLASSIFIER_PATH instead of a split-local fit	Split-local models everywhere; provenance sidecar
Judge failures indistinguishable from verdicts	High	llm_judge.py, run_evaluation.py	Fail-closed INJECTION carried no marker	JudgeResult.error; evaluation counts failures
Prompt construction: no system turn, breakable framing, None content unhandled	High	llm_judge.py, generate_answer.py	gpt-oss reasoning could exhaust max_tokens=300 $\rightarrow$ None $\rightarrow$ exception	System turn, tagged blocks, JSON mode, bounded reasoning, None handling
Benchmark at benchmark/ while code reads data/benchmark/; baseline git-ignored	Medium	layout, .gitignore	rebuild path broken on a fresh clone	Relocated; un-ignored; --from-baseline reproduces byte for byte
Duplicate requirements; deprecated Streamlit argument; misleading risk label	Low	requirements.txt, app.py	pip tolerated it; Streamlit warned	Cleaned

Actual bugs found in the first audit. Architectural, evaluation, benchmark and documentation findings and accepted limitations are in the README's development notes and Known limitations.

4. Root-cause investigation (first audit)

Observation	Shipped state	Meaning
Benign chunks (34) by ML band, max-sentence scoring	0 safe · 15 judge band · 19 above 0.70	19 chunks blocked with no review under the shipped routing
Reported false-positive sentence	'Please follow the steps below in order to reset your password.' = 0.767	Matches the 0.76–0.78 figure reported during development
Worst-scoring real sentences	'Managers must approve remote arrangements in writing.' = 0.79	Model learned authority/rule vocabulary, not 'aimed at the AI'
class_weight='balanced' alone	33/34 chunks move to the judge band, 0 to safe	Prior correction is not the fix; the model had never seen document prose
Group-held-out (no LLM), benign_seed fold	TP 23 · FP 31 · TN 0 · FN 0	Reproduces the reported collapse

Conclusion: a data-distribution problem, not a threshold problem. Moving HIGH_THRESHOLD would have hidden it.

Segmentation experiment (rerun on v3 with lineage grouping)

Benign sentence expansion	Strategy	Group-CV P / R / F1 / FPR	Held-out indirect detection	Benign doc chunks safe / judge / high	Poisoned injected chunk scores
off	whole	0.808 / 0.912 / 0.857 / 0.307	0.00	9 / 25 / 0	0.43, 0.59, 0.59
off	max_sentence	0.709 / 0.976 / 0.822 / 0.568	0.73	1 / 30 / 3	0.87, 0.83, 0.84
off	max_window2	0.778 / 0.952 / 0.856 / 0.386	0.40	1 / 33 / 0	0.64, 0.56, 0.82
on	whole	0.970 / 0.776 / 0.862 / 0.034	0.00	31 / 3 / 0	0.19, 0.36, 0.37
on	max_sentence	0.955 / 0.848 / 0.898 / 0.057	0.70	17 / 17 / 0	0.85, 0.70, 0.77
on	max_window2	0.971 / 0.816 / 0.887 / 0.034	0.10	26 / 8 / 0	0.46, 0.35, 0.75

Production choice: max-sentence scoring with benign sentence expansion. Whole-chunk scoring detects 0% of held-out indirect injections; max-sentence without expansion pushes almost every real chunk into the judge band and three above 0.70. The held-out indirect column now includes the ten novel payloads, which is why it reads 0.70 rather than 1.00.

5. What changed, file by file, and why

File	Change	Why
scripts/build_benchmark.py	REALISTIC_BENIGN_SEEDS (48 chunks); NOVEL_INDIRECT_PAYLOADS (10); lineage_id on every record with a frozen nearest-seed map; repair rows grouped per category; --from-baseline deterministic rebuild	Benign diversity was the root cause; attack lineage must be explicit; the committed benchmark must be reproducible offline
data/benchmark/	benchmark.jsonl is v3 (213); v1 and v2 frozen; baseline un-ignored	Preserve earlier versions for comparison; rebuild works on a fresh clone
ragshield/ml_classifier.py	training_units() adds each benign sentence as a label-0 unit; fit_classifier() shared by training and evaluation; provenance sidecar with library versions and embedding revision; environment-mismatch warning on load	Align training units with max-sentence inference; fold models trained like production; reproducibility
ragshield/heuristics.py	normalize(): NFKC, zero-width removal, confusable folding; base64 rescanner; 'disregard the earlier...' requires an instruction noun; mixed-script, fake-role-header and ai_addressed_instruction evidence rules	Disguised patterns must hit the same rules; a critical rule fired on a benign record; novel indirect payloads passed silently
ragshield/firewall.py	Routing table of section 2; ChunkResult gains band, decided_by, heuristic_matches, judge; batched Layer 2; ABLATION_NO_JUDGE sentinel	Fix the regression; make Layer 1 evidence useful; one routing implementation
ragshield/llm_judge.py	System turn + tagged block; JSON mode; gpt-oss: reasoning_effort low + include_reasoning false (no reasoning_format); qwen/minimax/deepseek: reasoning_format hidden; max_completion_tokens; None handling; JudgeResult.error	Security boundary; correct Groq parameters per current docs; failures distinguishable from verdicts
ragshield/generate_answer.py	System turn declaring retrieved text UNTRUSTED; tagged blocks; same reasoning parameter rules	Answer model must not treat document instructions as trusted
ragshield/config.py	Routing comments; env/Streamlit-secrets fallback for keys; pinned embedding revision; judge settings	Documentation drift; cloud deploy; reproducibility
scripts/run_evaluation.py	Split/fold-local models only; benign leak closed; judge accounting; error-source breakdown; lineage grouping with per-fold leakage assertions; lineage-clean category-held-out; per-template-group detection; provenance	Every number must come from a model that never saw its test data, including through a payload's other forms
scripts/train_classifier.py	Production model on all records; smoke test on a separate split; provenance	Evaluation no longer depends on the saved model
scripts/segmentation_experiment.py	Replaces test_segment_detection.py; lineage grouping	Evidence behind the scoring decision, reproducible
app.py	Fail-closed banner; sample-document loader; per-chunk band/layer/evidence/judge; auto-train if the model is missing; Evaluation tab shows grouping, lineage leakage status, per-group detection, lineage-clean column, staleness and judge-failure warnings	Explainability; honest display; works on a fresh clone or cloud deploy
tests/	87 unit tests + 2 slow: routing, heuristics (incl. in-sample vs held-out AI-addressed phrasings), judge parsing/fail-closed and exact Groq kwargs vs SDK signature, prompt boundaries, benchmark integrity/reproducibility/lineage, metric arithmetic, split leakage	Pin the routing table, security properties and evaluation validity
requirements.txt, .python-version, README, .gitignore, docs/	Exact version pins; README with both audits; models/ and results/ committed with hashes; report and screenshot scripts	GitHub and deployment readiness

6. Results (all produced by the committed code on the committed benchmark v3)

The committed evaluation runs used the live Groq judge (openai/gpt-oss-20b); results record llm_judge_used: true and zero judge failures. Layers 1+2-only figures (judge replaced by a 0.5 cutoff) are labelled as such and come from the segmentation experiment and the ablation conditions. The results files embed the benchmark's SHA-256; the app warns if it no longer matches.

6.1 Group-held-out cross-validation, grouped by lineage (headline)

Groups are attack lineages (all variants of one seed payload) plus benign document styles; a per-fold assertion guarantees no attack lineage is on both sides. Section 13.1 compares this with the older template-group split.

Fold	Train	Test	Groups held out	TP	FP	TN	FN	Precision	Recall	F1	FPR
1	157	56	8	25	1	30	0	0.962	1.000	0.980	0.032
2	174	39	9	24	0	14	1	1.000	0.960	0.980	0.000
3	174	39	10	25	0	14	0	1.000	1.000	1.000	0.000
4	172	41	9	23	0	16	2	1.000	0.920	0.958	0.000
5	175	38	9	25	0	13	0	1.000	1.000	1.000	0.000
Aggregate		213	45	122	1	87	3	0.992	0.976	0.984	0.011

Error sources (live judge): 3 of the 3 misses were judge verdicts (the chunk reached Layer 3 and was judged safe); 0 passed silently without review. 1 of the 1 false positives was a judge verdict.

Category	n	Rate	Meaning
direct_override	20	1.000	detected
role_manipulation	20	1.000	detected
prompt_extraction	15	1.000	detected
indirect_injection	30	0.967	detected
obfuscated	20	0.950	detected
paraphrased	20	0.950	detected
benign_hard_negative	88	0.989	correctly passed
Attack template group		n	Detection (full hybrid, live judge)
direct_override_gen_batch_0		2	1.00
direct_override_gen_batch_1		5	1.00
direct_override_gen_batch_2		2	1.00
direct_override_seed		8	1.00
indirect_article		5	1.00
indirect_cooking		5	1.00
indirect_meeting_notes		5	1.00
indirect_novel		10	0.90
indirect_tutorial		5	1.00
obfuscation_base64_wrap		7	1.00
obfuscation_homoglyph		6	0.83
obfuscation_zero_width		7	1.00
paraphrase_batch_0		6	1.00
paraphrase_batch_1		4	0.75

Attack template group	n	Detection (full hybrid, live judge)
paraphrase_batch_2	3	1.00
prompt_extraction_gen_batch_0	1	1.00
prompt_extraction_gen_batch_1	1	1.00
prompt_extraction_gen_batch_2	3	1.00
prompt_extraction_gen_batch_3	2	1.00
prompt_extraction_seed	6	1.00
repair_direct_override	3	1.00
repair_paraphrased	7	1.00
repair_prompt_extraction	2	1.00
repair_role_manipulation	6	1.00
role_manipulation_gen_batch_0	4	1.00
role_manipulation_gen_batch_1	3	1.00
role_manipulation_seed	7	1.00

Detection by template group under lineage grouping. `indirect_novel` (ten handwritten payloads sharing no wording with any seed) is the honest unseen-payload number: the classifier alone detects 1 of 10; with the `ai_addressed_instruction` rule escalating to Layer 3, the full hybrid detects 9 of 10 (live judge).

6.2 Ablation on the random 80/20 split

category	n	Heuristic	ML	Heuristic+ML	Full Hybrid
direct_override	5	0.4	1.0	1.0	1.0
role_manipulation	3	0.3333	1.0	1.0	1.0
prompt_extraction	4	0.5	0.75	0.75	1.0
indirect_injection	3	1.0	0.6667	0.6667	1.0
obfuscated	6	1.0	0.6667	0.8333	1.0
paraphrased	4	0.25	1.0	1.0	1.0
benign_hard_negative	18	1.0	0.9444	0.9444	1.0
Overall (F1)	43	0.75	0.8936	0.9167	1.0

Detection rate per attack category and correctly-passed rate for `benign_hard_negative`. Full Hybrid uses the live judge (20 calls, 0 failures), which is why it exceeds Heuristic+ML; the other three columns need no judge. The random split is optimistic by construction and is kept only to give the ablation one common test set.

6.3 Category-held-out (unseen attack family)

Held-out family	ML-only @0.5	Heuristic+ML	ML-only FPR	Train attacks sharing a lineage	Lineage-clean detection	By template group
direct_override	0.95	0.95	0.06	26 / 105	0.70	gen_batch_0=1.00; gen_batch_1=1.00; gen_batch_2=1.00; seed=1.00; repair_direct_override=0.67
role_manipulation	0.85	0.85	0.06	35 / 105	0.10	repair_role_manipulation=0.83; gen_batch_0=0.75; gen_batch_1=0.67; seed=1.00
prompt_extraction	0.87	0.93	0.06	26 / 110	0.60	gen_batch_0=1.00; gen_batch_1=1.00; gen_batch_2=0.33; gen_batch_3=1.00; seed=1.00; repair_prompt_extraction=1.00
indirect_injection	0.70	0.70	0.06	94 / 95	n/a	indirect_article=1.00; indirect_cooking=1.00; indirect_meeting_notes=1.00; indirect_novel=0.10; indirect_tutorial=1.00
obfuscated	0.40	0.55	0.06	94 / 105	0.00	base64_wrap=0.00; homoglyph=0.17; zero_width=1.00

Held-out family	ML-only @0.5	Heuristic+ ML	ML-only FPR	Train attacks sharing a lineage	Lineage-clean detection	By template group
paraphrased	0.90	0.90	0.06	47 / 105	0.20	paraphrase_batch_0=1.00; paraphrase_batch_1=0.50; paraphrase_batch_2=1.00; repair_paraphrased=1.00

Trained on every other family plus only the benign records outside the shared benign test set. 'Lineage-clean' additionally removes every training record sharing a lineage with the held-out family; for indirect_injection only one attack record survives, which is itself the finding: with 21 seed lineages, 'unseen family' and 'unseen payload' were not the same thing.

6.4 Real-document robustness

Model / scoring	Benign chunks SAFE without LLM	Sent to judge	Above 0.70	Poisoned injected chunks flagged
Shipped (v1 model, max-sentence)	0 / 34	15	19	3 / 3
v2 model (max-sentence, benign sentence expansion)	21 / 34	13	0	3 / 3
Final (v3 model, trained with the novel payloads)	17 / 34	17	0	3 / 3

Six fictional benign documents never used in training. Under the final system no benign chunk is blocked by Layers 1+2, half pass with no LLM call, and every injected chunk of the poisoned FAQ is hard-blocked by Layer 1 or escalated. The v3 model sends four more benign chunks to the judge than v2 did. tests/test_real_documents.py pins this behaviour.

7. Security boundary audit

#	Requirement	Status	How it is enforced / verified
1–3	Retrieved text cannot override the system prompt, developer instructions, or impersonate trusted instructions	Done	System turn states retrieved text is untrusted data; <retrieved_context> block with neutralised closing tags; test_generate_answer.py
4–5	Sanitised context contains only approved chunks; blocked chunks never reach generation	Done	sanitised_context() joins final_included only; test asserts the attack string is absent from the messages sent
6–8	Judge failures, malformed responses and API errors fail closed	Done	INJECTION with error class for API exceptions, None content, unparseable JSON, invalid verdict; real SDK connection failure exercised offline
9	Critical heuristic matches hard-block	Done	Routing row 1; zero critical fires on 88 benign records
10–13	Direct, indirect, role-manipulation and prompt-extraction attacks detected	Verified incl. live judge; honest gaps stated	Lineage CV, full hybrid with live judge: direct 1.00, role 1.00, extraction 1.00, indirect 0.97; novel indirect payloads 0.10 by the classifier alone, 0.90 with Layer 1 escalation and the live judge
14–15	Obfuscation and paraphrase tested	Verified, limitation noted	All 20 obfuscated records leave Layer 1 evidence; classifier alone 0.40–0.55; paraphrased 0.90
16	Legitimate instructional content not automatically blocked	Done	High ML score alone never blocks; 0 of 34 real benign chunks hard-blocked
17	User query and document content clearly separated	Done	Separate tagged blocks in both prompts
18	Answer generation cannot treat document instructions as trusted	Done (best effort)	Prompt boundary; documented as defence in depth, not a formal guarantee

8. Streamlit application walkthrough

Captured from the running app in a headless browser after all fixes (docs/capture_screenshots.py). They show what a user sees with the Groq key configured and Layer 3 active.

RAGShield Evaluation

Group-held-out cross-validation (headline)

StratifiedGroupKFold grouped by lineage (lineage_id (attack seed lineage; benign:<template_group> for benign)); 45 groups, 31 attack lineages. Every fold fits its own classifier and runs the real firewall on groups it never saw. Every attack in the benchmark descends from one of 21 seed sentences (obfuscated, indirect and paraphrased records are transforms of them), so grouping by lineage keeps all variants of a payload on one side of the split. Attack-lineage leakage into training: none.

LLM judge: enabled (openai/gpt-oss-20b) · seed 42 · routing bands [0.3, 0.7] · ML measurement cutoff 0.5

Overall (F1)	43	0.75	0.8936	0.9167	1

Category-held-out: unseen attack families

For each family the classifier is trained on every OTHER family (and only benign records outside the shared benign test set), then tested on the held-out family plus that benign set. 'ML-only' is Layer 2 at the 0.5 cutoff; 'Heuristic+ML' is the no-LLM firewall routing.

'train attacks sharing a lineage' shows how much of the training set descends from the same seeds as the held-out family; 'lineage-clean' removes those records before training. Low lineage-clean numbers mean the classifier recognises payloads it has seen in another form rather than injection intent in general.

(continued) Figure 5.

category	ML-only detection	Heuristic+ML detection	ML-only FPR	train attacks sharing a lineage	lineage-clean detection
direct_override	0.95	0.95	0.0556	26/105	0.7

results/ metrics.json · ablation_matrix.csv · group_held_out_metrics.json (+ _template_group.json) · segmentation_experiment.json tests/ pytest suite docs/ this report, build_report.py, capture_screenshots.py, screenshots/ app.py · README.md

Quick start

```
python -m venv .venv && source .venv/bin/activate (Windows: .venv\Scripts\activate)
pip install -r requirements.txt
cp .env.example .env # add GROQ_API_KEY
python scripts/train_classifier.py
python scripts/run_evaluation.py
python scripts/run_evaluation.py --group-held-out
pytest && pytest -m slow
streamlit run app.py
```

10. Live Groq verification

Layer 3 was run live against Groq (openai/gpt-oss-20b). The lineage-grouped cross-validation made 118 judge calls and the random-split evaluation 20, with 0 judge failures in total; both runs are recorded in results/ with llm_judge_used: true. Only runs showing judge_failures: 0 are quoted; a rate-limited run must be repeated after the quota recovers. Judge accuracy is measured on a small benchmark (213 records), so confidence intervals are wide.

11. Resume defensibility

3-layer firewall: intact and consistent across code, evaluation and documentation, with a routing table that can be explained in one sentence per row. **Adversarial benchmark:** direct, obfuscated (zero-width, base64, homoglyph), paraphrased, indirect (seed-derived and novel) and extraction attacks plus 88 hard benign negatives across nine styles; explicit attack lineage; deterministic rebuild; integrity tests. **Rule-based vs ML vs hybrid comparison:** four-condition ablation with precision, recall, F1 and FPR per attack type, category-held-out (naive and lineage-clean) and lineage-grouped cross-validation, with leakage closed and judge failures accounted for. The honest headline is the lineage-grouped table; the honest caveat is that the classifier does not generalise to genuinely new payloads on its own, and the design relies on Layer 1 escalation and Layer 3 for those.

12. Next steps: adding the key, pushing to GitHub, deploying

12.1 Confirm Layer 3 works locally

```
cp .env.example .env # then edit: GROQ_API_KEY=gsk...
streamlit run app.py
```

Load the sample documents and ask *How do I reset my online banking password?* The password-reset chunk must show *Verdict: SAFE* with a confidence (not 'Judge unavailable'), and the Final Answer section must contain a generated answer. Then ask *How do I reset the thermostat to factory settings?* and confirm the poisoned chunks are still blocked. 'Judge call failed (rate_limited)' means quota, not a bug; wait and retry.

12.2 Reproduce the LLM-backed evaluation

```
python scripts/run_evaluation.py
python scripts/run_evaluation.py --group-held-out
```

12.3 Pre-push checklist

Check	Command	Expected
Tests pass	<code>pytest && pytest -m slow</code>	87 passed; 2 passed
No secrets in the tree	<code>grep -r "gsk_" --include=*.py --include=*.md --include=*.toml .</code>	no output
Ignored files really ignored	<code>git status --ignored</code>	<code>.env</code> , <code>.venv/</code> , <code>data/documents/</code> listed under ignored
Results match benchmark	open Evaluation tab	no 'hash mismatch' warning

12.4 Push to GitHub

```
cd rag-shield
git init -b main
git add .
git commit -m "RAGShield: 3-layer RAG prompt-injection firewall with reproducible evaluation"
git remote add origin https://github.com/<your-user>/rag-shield.git
git push -u origin main
```

`models/` (about 5 KB) and `results/` are committed deliberately so a fresh clone and the cloud deploy work immediately; both carry the benchmark hash. `.env`, `.venv/` and uploaded documents are ignored.

12.5 Deploy on Streamlit Community Cloud

Step	What to do
1	Sign in at share.streamlit.io with GitHub and choose New app .
2	Repository: your rag-shield repo · Branch: main · Main file path: <code>app.py</code> .
3	Advanced settings → Python version 3.12 (matches <code>.python-version</code> and the pinned wheels).
4	Advanced settings → Secrets : paste <code>GROQ_API_KEY = "gsk_..."</code> (TOML). <code>config.py</code> reads the environment first and Streamlit secrets second.
5	Deploy. First start takes about a minute (downloads the pinned MiniLM revision). If <code>models/</code> were missing the app trains the classifier itself on first start (verified).
6	Verify with the two demo questions from 12.1, then share the URL (Settings → Sharing).

Operational notes: uploaded documents live on the container disk and vanish on restart (intended single-session design); the free tier sleeps after inactivity; Groq free-tier rate limits are per minute, so bursts can produce fail-closed 'rate_limited' cards, which the UI labels explicitly.

13. Second audit: lineage leakage, Groq configuration, reproducibility, GO/NO-GO

13.1 Attack lineage leakage (the most important finding)

The benchmark builder was traced end to end. Every attack in v1/v2 descends from one of 21 handwritten seed sentences: obfuscated rows are deterministic transforms of a seed (zero-width insertion, base64 wrapping, homoglyph substitution), indirect rows embed a seed verbatim in one of four benign wrappers, and the LLM-generated same-style and paraphrased rows were produced from a seed. Recovering lineage: 61 rows invert exactly (21 seeds, 20 wrappers, 20 de-obfuscations); the 54 LLM-generated and curated rows were mapped to their nearest seed by MiniLM cosine similarity (0.35 to 0.84) and the mapping frozen in the builder. 20 of the 21 lineages span more than one category.

Consequence: the previous category:template_group grouping let a payload sit in training as a plain seed while its wrapped form sat in test. Under that grouping 13 to 15 attack lineages leaked into training in every fold, and category-held-out for indirect_injection trained on 94 of 95 attack records sharing a lineage with the held-out set. The reported indirect detection of 1.00 was payload memorisation, exactly as suspected.

Changes: (1) lineage_id on every record (benign rows use benign:<template_group>); (2) group-held-out groups on lineage by default, with a per-fold assertion that no attack lineage appears on both sides, and --group-by template_group retained for comparison; (3) a lineage-clean variant of category-held-out; (4) ten novel indirect payloads with new intents (goal hijacking, output manipulation, exfiltration, language lock-in) that share no wording with any seed, each its own lineage. Nothing was removed; v2 is frozen as benchmark_v2_203.jsonl.

Group-held-out	precision	recall	F1	FPR	TP / FP / TN / FN	lineage leakage
lineage grouping, v3, Layers 1+2 (no judge)	0.955	0.848	0.898	0.057	106 / 5 / 83 / 19	none (asserted)
lineage grouping, v3, full hybrid (live judge; current headline)	0.992	0.976	0.984	0.011	122 / 1 / 87 / 3	none (asserted)
template_group grouping, v3, Layers 1+2 (no judge)	0.972	0.824	0.892	0.034	103 / 3 / 85 / 22	13 to 15 lineages per fold
template_group grouping, v2, Layers 1+2 (first report)	0.962	0.887	0.923	0.045	102 / 4 / 84 / 13	present

Honest reading: the leakage-free Layers 1+2 recall is 0.848, not 0.887; the novel indirect payloads are detected by the classifier at 0.10; lineage-clean category-held-out ranges from 0.00 (obfuscated) to 0.70 (direct_override). The classifier recognises payloads it has seen in another form far better than injection intent in general, which is why it is one layer of three.

13.2 Closing the gap the novel payloads exposed

In leakage-free CV, 7 of the 10 novel payloads scored below LOW_THRESHOLD with no Layer 1 evidence: they passed silently and Layer 3 never saw them. Their shared marker is text that addresses the AI reading the document ('note to any AI assistant summarizing this listing', 'if you are a language model', 'support assistant, when you respond', 'whoever processes these minutes automatically should'). A non-critical Layer 1 rule, ai_addressed_instruction, was added for that pattern. Method, in order: five extra payloads were written before the rule was designed; the rule was designed on the ten benchmark payloads only; it was checked against all 88 benign records and 34 sample-document chunks (zero matches) and against every other attack (zero matches). Result: 9 of 10 in-sample payloads and 3 of 5 held-out phrasings are escalated; the held-out five live in the test suite, not the benchmark. Silent passes in leakage-free CV went from 7 to 0; aggregate precision/recall/F1 are unchanged because the ablation's 0.5 cutoff still counts a review-band record as a miss. The rule never blocks on its own.

13.3 Groq request configuration

Checked against console.groq.com/docs/reasoning and /docs/structured-outputs and against the installed SDK signature (groq 0.37.1). For gpt-oss models Groq accepts reasoning_effort in {low, medium, high} and include_reasoning, and does NOT support reasoning_format; reasoning is returned in message.reasoning, never inside content. JSON object mode is available on all models and requires the prompt to ask for JSON, which the system prompt does. The judge sends

temperature 0, max_completion_tokens 600 (not the older max_tokens), response_format json_object, reasoning_effort low and include_reasoning false for gpt-oss; reasoning_format hidden for qwen/minimax/deepseek families (raw + JSON mode is a 400); nothing extra for non-reasoning models. include_reasoning and reasoning_format are never sent together. tests/test_llm_judge.py pins the exact kwargs, checks every kwarg against the installed SDK signature, and exercises the full request/response path with a mocked client; the same configuration was then run live (section 10).

13.4 Reproducibility

requirements.txt pins the exact versions the committed classifier and results were produced with: Python 3.12.2 (.python-version), scikit-learn 1.9.1, sentence-transformers 5.7.0, transformers 5.17.0, torch 2.14.0, numpy 2.5.3, faiss-cpu 1.15.0, groq 0.37.1, streamlit 1.63.0, pandas 3.0.5, joblib 1.6.0, pypdf 6.18.0. The embedding model is pinned to Hugging Face revision 1110a243fdf4706b3f48f1d95db1a4f5529b4d41 in config.py and used by both the classifier and the retriever. The classifier sidecar records Python, scikit-learn, sentence-transformers, torch and numpy versions, the embedding revision, training-unit counts and the benchmark SHA-256; load_classifier() warns when the running environment differs. The model was retrained and every evaluation rerun after the pins and the benchmark change.

13.5 Verification checklist

Item	How verified	Result
Benchmark counts, duplicates, empty records	tests/test_benchmark.py; --from-baseline byte-for-byte rebuild	213 records, counts match targets, 0 duplicates, 0 empty
Train/test leakage (benign)	category-held-out excludes shared benign test rows; split-local models only	closed
Attack lineage leakage	lineage_id on every record; per-fold assertion; tests/test_evaluation.py	0 lineages leak under lineage grouping; 13–15 under old grouping (documented)
Group / category-held-out splits	StratifiedGroupKFold(5, shuffle, seed 42); every fold has benign rows	verified
Threshold selection	0.30 / 0.70 unchanged since v1; 0.5 is a measurement cutoff only	no tuning on held-out data
Metric arithmetic	test_compute_metrics_arithmetic (hand-computed confusion matrix)	correct
Production vs evaluation routing	both call firewall.screen_chunks; ABLATION_NO_JUDGE sentinel for no-LLM	single implementation
Layer 1/2/3 behaviour	routing tests with fakes; heuristics tests incl. obfuscation and AI-addressed rule	87 unit tests pass
Judge failure handling	mocked rate limit / empty / malformed / invalid verdict; real SDK connection failure offline	fails closed with labelled error
Prompt boundary / context sanitisation	system turn, tagged blocks, neutralised closing tags; blocked text absent from answer messages	tests pass
Streamlit behaviour	driven headlessly: load samples, poisoned query, benign query, evaluation tab; auto-train when model missing	no errors
Provenance / benchmark hash	model sidecar and results carry SHA-256; app warns on mismatch	all match current benchmark
Groq request + JSON parsing	kwargs pinned and checked against SDK signature; parser tests	pass; live run completed with 0 judge failures
Dependency compatibility	exact pins; embedding revision pin; environment recorded and checked on load	pinned; model retrained under the pinned stack

13.6 Verdict: GO, with one stated limitation

GO for publishing the repository and deploying the app. The architecture survived the audit: the problems found were in the benchmark's construction and the evaluation's split, not in the three-layer design, and they are now measured honestly. Layer 3 has been exercised live (section 10). The remaining limitation is not hidden: the classifier's generalisation to genuinely new payloads is weak (1 of 10 novel indirect payloads; lineage-clean 0.00 to 0.70). The design covers this with Layer 1 escalation and Layer 3 review, and the README says so in plain terms. Do not describe the classifier as detecting unseen attacks on its own.
